†Members of the *Pseudomonas aeruginosa* KPC Group are given in the Acknowledgements section.

**Keywords:** clone, multidrug resistance, outbreak

Sir,

The emergence of *Klebsiella pneumoniae* carbapenemase (KPC) has now become a global concern. KPC producers are mostly Enterobacteriaceae, but *Pseudomonas aeruginosa* have also been reported and mostly identified in the American continent. However, it is unknown if this is due to the spread of epidemic strains, since the multilocus sequence type (ST) has not been provided in most of those reports. The aim of this work was to characterize KPC-producing *P. aeruginosa* isolated in Argentina from 2006 to June 2011.

Since 2005, we designed an algorithm to detect carbapenemases (metallo-β-lactamases, KPC, etc.) in *P. aeruginosa* at the level of the clinical microbiology laboratory, which was implemented among 432 hospitals. All *P. aeruginosa* were screened through that algorithm, and KPC production was suspected in isolates with high-level resistance to carbapenems and aztreonam (absence of disc zones) and a negative synergy test result between the carbapenems and EDTA, a phenotype consistent with the reported patterns of KPC-producing *P. aeruginosa*. As a result, 65 isolates were suspected to be KPC producers (Table 1). Strains were isolated from nine hospitals (seven cities, five provinces), six of which were located in the Patagonia region. The first KPC producer was detected in a hospital from Bariloche in 2006. Dissemination to other locations (except Chaco) was associated with patients previously hospitalized in Bariloche (Table 1).

A subset (n=30) of suspected isolates was submitted to the National Reference Laboratory (Malbrán Institute), where *bla*<sub>KPC-2</sub> was confirmed in all strains by PCR/sequencing. XbaI PFGE analysis, using previously described criteria,5 revealed that all but one of the isolates belonged to a single pulsotype (Table 1). In Argentina, these PFGE patterns had not previously been observed. Multilocus sequence typing of one strain of each PFGE type revealed that the dominant clone (PFGE type A) belonged to ST654, while the unique strain of PFGE type B (Chaco), belonged to ST162 (http://pubmlst.org/paeruginosa) (Table 1).

To investigate the genetic organization of *bla*<sub>KPC-2</sub> in *P. aeruginosa*, we used PCR primer pairs located in the Tn4401 structure and in the flanking sequences found in Enterobacteriaceae with KPC in our country, called Variant 1a (ISKpn8 and ISKpn6-like).6 All isolates belonging to ST654 harboured *bla*<sub>KPC-2</sub> in Tn4401b, which was confirmed by sequencing. The ST162 isolate harboured *bla*<sub>KPC-2</sub> in Variant 1a.6 By plasmid content analysis and Southern blotting with a *bla*<sub>KPC-2</sub> probe,6 we found that ST654 contains *bla*<sub>KPC-2</sub> in a plasmid of 50 kb, while the strain ST162 contains several plasmids but only one of 47 kb hybridized with KPC. Plasmid incompatibility (Inc) groups were further analysed using the PCR-based replicon-typing protocol described for Enterobacteriaceae.7 Both ST162 and ST654 gave negative results for all the Inc groups tested.

The strains were highly resistant (MICs >128 mg/L) to aztreonam, cefepime, imipenem, meropenem and piperacillin/tazobactam by agar dilution. Colistin (MICs 1 mg/L), gentamicin (MICs 2 mg/L) and amikacin (MICs 4 mg/L) were the most active drugs. ST162 was susceptible to ciprofloxacin (MIC 0.5 mg/L) (Table 1).

The origin of *bla*<sub>KPC-2</sub>-possessing ST654 remains uncertain. The mobilization of *bla*<sub>KPC-2</sub> from Enterobacteriaceae was ruled out: first, these strains were not detected in Bariloche until 2010 and, second, they harboured *bla*<sub>KPC-2</sub> in the Variant 1a.6 ST162 was isolated from a patient with no recent history of travel. Interestingly, this patient shared the same ward simultaneously with two other patients undergoing infections due to KPC-producing *Enterobacter cloacae* and *K. pneumoniae*. In these isolates, the *bla*<sub>KPC-2</sub> genetic environment matched that of ST162. However, *bla*<sub>KPC-2</sub> in *E. cloacae* and *K. pneumoniae* was associated with plasmids of different sizes (40 and >150 kb, respectively) and different Inc groups (N and FIIS, respectively)6 from that detected in ST162. Thus, we speculated that the surge of ST162 could be due to *bla*<sub>KPC-2</sub> mobilization among different plasmids (i.e. transposition).

Clonal complexes CC111 and CC235 have been reported as the major clones involved in the global dissemination of extended-spectrum and metallo-β-lactamases in *P. aeruginosa*.8 However, we observed that the main dissemination of KPC was mediated by a new clone (ST654) not related to both CC111 and CC235. ST654 is endemic in Singapore,9 where it has been

fThe respective index patients of these locations were previously hospitalized in Bariloche.
gJanuary–June 2011.

acknowledged and named as Pseudomonas aeruginosa KPC group. It was first identified in Sweden as a VIM-2 producer, although the isolate was imported from Tunisia.10 Unlike other Latin American regions, such as Puerto Rico and Colombia, where different PFGE types and STs have been identified,14 the dissemination of KPC-producing P. aeruginosa in Argentina is mainly associated with a single clone. These findings confirm that ST654 plays an important role in the global spread of carbapenemases, either metallo-β-lactamases or KPC. Thus, the worldwide dissemination of KPC-producing P. aeruginosa of ST654 might be expected and should be monitored.
